Network Applications Programming - Homework 2 (FTP program with data compression)

Motivation:

FTP is a common network service. Since you have learned how to write UNIX socket programs in class, this homework asks you to practice the socket programming skill.

Homework Content:

You need to provide the <u>FTP service</u> in the homework. By using TCP sockets, you can create a FTP server and a FTP client. Your FTP client has to support some commands:

► **link** IP_addr port_num:

Connect to a server. Your program should allow users to specify the IP address and port number of a server. Notice that the server side needs to print out the client's connection information (e.g., IP address, port #, socket type, etc.)

> leave:

Terminate the connection. The server side has to also show the leave of the client.

> **send** filename:

Upload a file called "filename" to the server. Your FTP service should also support non-textual files, for example, MP3 or WORD files. Moreover, you need to provide file compression to save the transmission time. In particular, you can use <u>fixed-length Huffman coding</u> to compress the file. When you use the "send" command, your client in fact should send two separated files to the server:

- 1) The coded version of "filenanme".
- 2) Necessary information related to Huffman coding (e.g., the appearing frequency of each alphabet in the file).

Here are some examples of the above commands:

Client side (140.113.1.1)

[student @ CSE ~]\$ link 140.113.1.2 3456

The server with IP address "140.113.1.2" has accepted your connection.

[student @ CSE \sim]\$ send 1.txt

Original file length: 140,234 bytes, compressed file length: 23,768 bytes (ratio: 16.95%)

Time to upload: 2021/3/24 13:20

Using fixed-length codeword (3 bits)

[student @ CSE ~]\$ leave

Bye bye.

Server side (140.113.1.2 port 1234)

[TA @ CSE ∼] server # TA runs the server program

A client "140.113.1.1" has connected via port num 1732 using SOCK_STREAM (TCP)

The client sends a file "1.txt" with size of 140,234 bytes. The Huffman coding data are stored in "1-code.txt".

TA will open "1.txt" here to test its correctness. Also, TA will check the "1-code.txt" file # to make sure that you indeed compress the file via Huffman coding.

The client "140.113.1.1" with port 4323 has terminated the connection.

Below gives some format of the Huffman coding-related information:

Fixed-length Huffman coding (3-bit codeword):			
Alphabet (ASCII code)	Frequency (%)	Codeword	
A (65)	140,231 (21.45%)	000	
B (66)	50,123 (7.67%)	001	
C (67)	63,154 (9.66%)	010	
Z (90)	234,453 (35.86%)	011	

Requirements:

- You need to use **UNIX socket programming** in this homework.
- You have to provide a <u>makefile</u>. TAs will deduct your grades if there is no makefile, or the makefile is erroneous.
- You must submit a README file along with your program. The README file should briefly describe how you write your codes (for example, the idea of your program).
- You have to demonstrate your program. TAs will announce the demonstration time.

Grading Policy:

You need to submit your codes and demonstrate your program to TAs. The due day of this homework is **4/14**. You will get **no point** if you do NOT demonstrate your program (even though you submit codes). Discussion among your classmates is encouraged. However, plagiarists will get **ZERO point**. Below are the points you can get in this homework:

Items	Points
Socket connection (i.e., link and leave commands on the client side and	10%
the connection information on the server side)	
File transmission	20%
Huffman coding	50%
User interface (for example, welcome message or help command)	10%
Code's comments and README file	10%
Bonus: You ALSO provide variable-length Huffman coding.	
[Note] If you implement only variable-length Huffman coding (without	20%
the fixed-length one), you will NOT get this bonus.
